### Description

Newly introduced keyword follow a different logic compared to previous one. For example, if we take `http_user_agent`, it applies on content placed before it. This is the contrary for a keyword like `tls_sni`. But the information provided by `list-keywords` are the same:

```
=tls_sni=
Description: content modifier to match specifically and only on the TLS SNI buffer
Features: No option, payload inspecting keyword
```

```
=http_user_agent=
Description: content modifier to match only on the HTTP User-Agent header
Features: No option, payload inspecting keyword
```

Consequence is that user has not enough information to know how to use it.

At minimum I propose we use context setter instead of content modifier

Content modifier is a term that we just use for certain types of keywords.

I think this issue is mostly fixed.
